## LIST OF TABLES

Table 1: Junction Falls Concrete Quantities Summary.....	5
Table 2: Powell Falls Concrete Quantities Summary .....	6

# 1 Structural Removal Quantities

Calculations for the concrete, reinforcement, and masonry quantities at Junction Falls and Powell Falls were made using available plan sets for each site. The available drawings were not comprehensive, and various assumptions and estimations had to be made for both locations. Efforts were made to keep any necessary estimations, to a reasonable degree, conservative. The measuring tool of Bluebeam Revu, which can derive length and size estimations based on the scale of a drawing sheet, was heavily utilized for the calculations at each site.

Neither site provided sufficient data on the concrete reinforcement to determine precise steel quantities. Accordingly, an estimate of 2% rebar by concrete volume was made to estimate the amount of rebar at each location. Concrete and masonry quantities were given in cubic yards, rounded to the nearest tenth, and rebar quantities were given in tons of steel, rounded to the nearest whole number.

## 1.1 Junction Falls Quantities

The plan sheets utilized for the Junction Falls estimate were prepared by Ayres Associates in 1990 for a rehabilitation project at the site. The plans focus on the areas that were to be rehabbed for that project. Many details for the remaining areas were not provided. The full calculations are included as Attachment I-1 to this Appendix. The plan sheets used for estimate are included as Attachment I-2.

### 1.1.1 Elements, Estimates, and Assumptions

The structural elements for the Junction Falls quantities included the primary spillway, the left and right abutments and wingwalls/retaining walls, the upstream parapet walls, the penstock, and the powerhouse building. The powerhouse building is comprised of a concrete base with a masonry section on top.

Notable estimates and assumption for the Junction Falls quantities include the following:

- For the abutments and wingwalls/retaining walls, an average width often had to be estimated as it was not clearly shown how far into the earthen embankments the elements extend.
- The depth of the upstream parapet walls had to be estimated as no values were provided in the plans.
- Most dimensions for the penstock had to be estimated, as only a very approximate cross section and layout is shown on the plans.
- No information was provided for the brick portion of the powerhouse building so all dimensions had to be estimated based on the values of the underlying concrete portion.
- There is an additional masonry building downstream of the powerhouse, approximately at the water level. No information was provided for this structure. A conservative estimate of 75% of the masonry quantity for the powerhouse was made for this structure.

### 1.1.2 Results

The structural quantities for Junction Falls were estimated to be 3,583.1 cubic yards of concrete, 471 tons of steel reinforcing, and 19.6 cubic yards of masonry. The results for the concrete, broken down by element, are summarized in **Table 1**, below.

**Table 1: Junction Falls Concrete Quantities Summary**

Element	Quantity (yd. <sup>3</sup> )
Spillway	2192.1
Left Abutment/Wingwall	200.1
Right Abutment	685.0
Upstream Parapet Walls	101.6
Penstock	140.7
Right Retaining Wall	72.2
Powerhouse	191.4
<b>Total</b>	<b>3583.1</b>

## 1.2 Powell Falls Quantities

The plan sheets utilized for the Powell Falls estimate were developed by Ayres Associates for a 1992 rehabilitation at the site. Additionally, photos were used from a 2021 Decommissioning Plan also developed by Ayres Associates. The plans focus on the areas that were to be rehabbed for that project. Many details for the remaining areas were not provided. The full calculations are included as Attachment I-3 to this Appendix. The plan sheets used for estimate are included as Attachment I-4.

### 1.2.1 Elements, Estimates, and Assumptions

The structural elements for the Junction Falls quantities included the spillway, abutments, wingwalls, wasteway, intake bay, tailrace, and powerhouse.

Notable estimates and assumption for the Junction Falls quantities include the following:

- Cross sections of the right and left abutments are not shown on the plans. The abutments were conservatively assumed to have a rectangular cross section that extends out as far as the abutting spillway cross section.
- Cross sections of the wasteway wingwalls were not provided and had to be estimated.
- The upstream wasteway wingwall was not shown on any of the plan sheets. It was estimated from photos to be 75% of the volume of the downstream right wasteway wingwall.
- The layout of the floors on the downstream section of the powerhouse is difficult to assess from the given plans and photos. Conservative assumptions were made in the estimate of these concrete quantities.

- Assumptions had to be made when quantifying how much of the powerhouse walls are brick and how much of the walls are concrete blocks.
- The top and bottom elevations of the tailrace are not specified and had to be assumed.
- The abutment/retaining wall on the east side of the intake bay is not accounted for in the drawings. The length and thickness of this wall is not known, and sufficient photos are not available to make a proper estimate. To account for this structure and possible additional concrete features such as retaining walls not shown in the available drawings, an additional 30 cubic yards was added to the concrete estimate.

## 1.2.2 Results

The structural quantities for Junction Falls were estimated to be 1,354.1 cubic yards of concrete, 178 tons of steel reinforcing, and 14.0 cubic yards of masonry. The results for the concrete, broken down by element, are summarized in Table 2, below.

**Table 2: Powell Falls Concrete Quantities Summary**

Element	Quantity (yd. <sup>3</sup> )
Main Spillway and Abutments/Wingwalls	1012.7
Wasteway, Intake Bay, and Tailrace	177.7
Powerhouse	133.7
Miscellaneous Additional Concrete	30.0
<b>Total</b>	<b>1354.1</b>

## 2 Winter Street Bridge Concrete Footing Addition

There is concern that dewatering and removal of Junction Falls Dam may lead to scour of the Winter Street Bridge piers, which are located just upstream of the dam. Additional analysis on this potentiality is recommended for the Pre-construction, Engineering, and Design (PED) phase.

The as-built plans for Winter Street Bridge call out a 9-foot-thick foundation seal. In theory, this seal should provide a good contact between the rock and the bridge pier foundation. However, the condition of the seal and its effectiveness is currently unknown. It is assumed that the normal water level will be roughly one foot deep when the area is dewatered. After removal of Junction Falls Dam, sediment should be removed from around the bridge pier foundation and an inspection and an assessment of the conditions completed.

One possibility being considered is to add a triangular concrete wedge around the perimeter of the footing to improve the seal and protect the adjacent bedrock. The contractor would have to clear any remaining sediment away from the bridge footing before placing the concrete. After the concrete is added, rock scour protection would be placed above and around the triangular concrete wedge at the footing. A scour evaluation is recommended during the design phase to design scour protection at the Winter Street Bridge pier.

## **2.1 Concrete Addition Quantities**

Calculations were completed to estimate the concrete and rebar quantities for the potential concrete addition at the Winter Street Bridge footing. An estimate of 2% rebar to concrete volume was made. These calculations can be found in Appendix Attachment I-5. Additionally, relevant as-built drawings for the bridge can be found in Appendix Attachment I-6.

### **2.1.1 Results**

The calculations conservatively estimated a concrete quantity of 20 cubic yards and a rebar quantity of 2.6 tons for the Winter Street Bridge footing addition.

## **3 2021 Ayres Powell Falls Decommissioning Report**

A decommissioning plan was prepared by Ayres Associates for Powell Falls and detailed in a 2021 report, written for the City of River Falls. The report details a removal and restoration plan for Powell Falls, including construction methodology, sequencing, and schedule. Annotated drawings from this report are attached to this appendix as Attachment I-7. The full report can be found at the following link:

[https://www.rfmu.org/DocumentCenter/View/4316/Powell-Falls-Decommissioning-Plan\\_Ayres20210130](https://www.rfmu.org/DocumentCenter/View/4316/Powell-Falls-Decommissioning-Plan_Ayres20210130)

## **4 2017 Inter-Fluve Dam Removal Feasibility Report**

A feasibility report was written by Inter-Fluve in 2017 for Friend of the Kinni regarding restoration of the Kinnickinnic River through dam removal. This report includes detailed proposals for dam access, dewatering, and removal for both Junction Falls and Powell Falls. These sections of the report are included as Attachment I-8 to this appendix.

Project

## Junction Falls Quantity Estimate Calculations

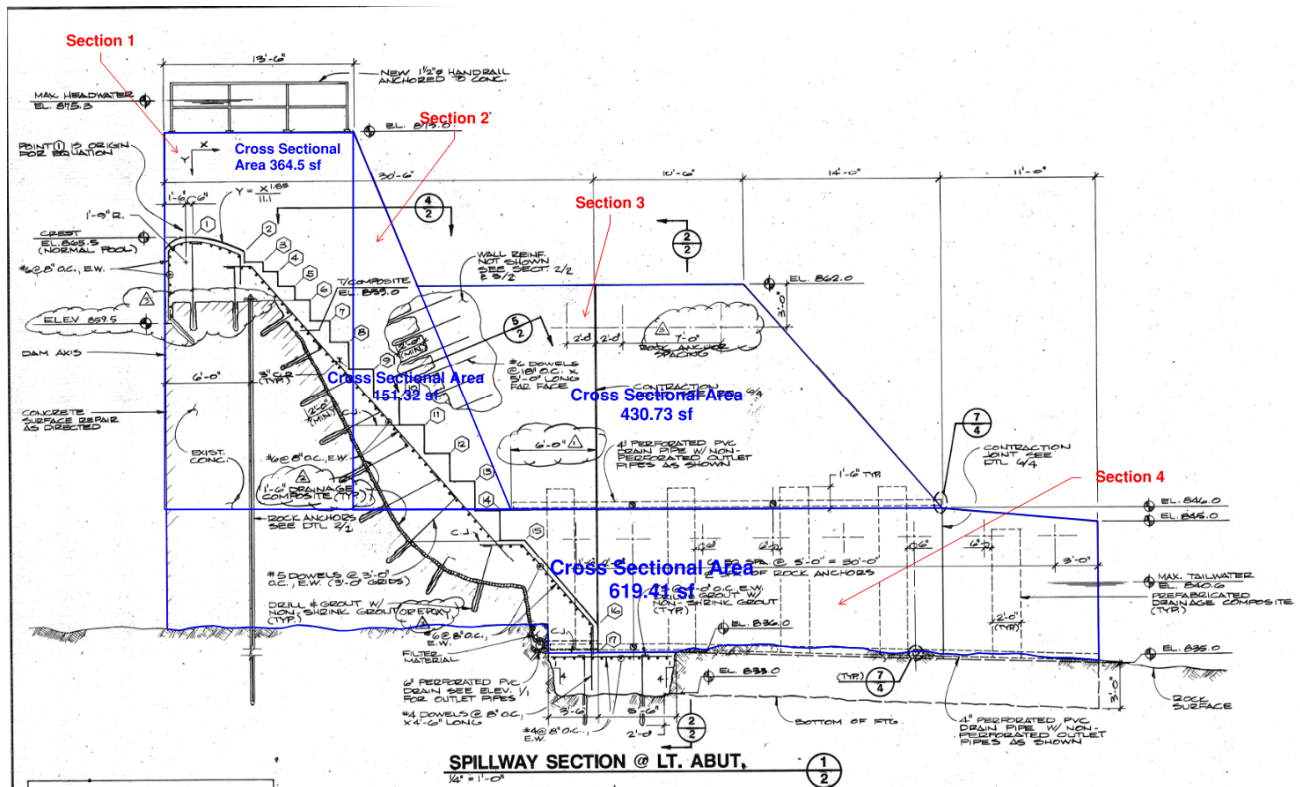

### Concrete Quantities

#### Spillway

Spillway cross sectional area, estimated using Bluebeam Revu: 516.16 sf.  
 Length, given in downstream elevation view drawing: 114'-8" = 114.66 ft.  
 Volume = 516.16 sf x 114.66 ft. = 59186.3 cf = 2192.1 cy

## Left Abutments/Wingwall/Retaining Wall

### Section 1:

Cross Sectional Area (calculated using given widths and elevations) = 364.5 sf

Width of abutment varies. Estimate average of 4 feet.

Volume =  $364.5 \text{ sf} \times 4 \text{ ft} = 1485 \text{ cf} = 54 \text{ cy}$

### Section 2:

Cross Sectional Area, estimated using Bluebeam Revu set to scale of drawings = 151.32 sf

Width of abutment varies. Estimate average of 4.0 feet wide.

Volume =  $151.32 \times 4.0 \text{ ft} = 605.28 \text{ cf} = 22.4 \text{ cy}$

### Section 3:

Cross Sectional Area, estimated using Bluebeam Revu set to scale of drawings = 430.73 sf

Upper Wingwall/retaining wall width given as 2 ft.

Volume =  $430.73 \text{ sf} \times 2 \text{ ft} = 861.46 \text{ cf} = 31.9 \text{ cy}$

### Section 4:

Cross Sectional Area, estimated using Bluebeam Revu set to scale of drawings = 619.41 sf

Lower Wingwall/retaining wall width varies. Estimate 4 ft. average.

Volume =  $619.41 \text{ sf} \times 4 \text{ ft} = 2477.6 \text{ cf} = 91.8 \text{ cy}$

Total Left Abutment + Wingwall Concrete Estimate =  $54 + 22.4 + 31.9 + 91.8 = 200.1 \text{ cy}$

## Right Abutment

### Primary Abutment Section:

Cross Sectional Area, estimated using Bluebeam Revu set to scale of drawings = 646.64 sf

Width of abutment varies, use approximate average width of 24.8 ft.

Volume =  $646.64 \times 24.8 \text{ ft} = 16036.7 \text{ cf} = 594.0 \text{ cy}$

Subtract out wasteway:

Cross Section =  $5 \text{ ft} \times 5 \text{ ft} = 25 \text{ sf}$

Length = 23.146 ft

Volume =  $25 \text{ sf} \times 23.146 \text{ ft} = 578.65 \text{ cf} = 21.4 \text{ cy}$

Primary Abutment Section Volume =  $594 \text{ cy} - 21.4 \text{ cy} = 572.6 \text{ cy}$

### Footing:

Cross Sectional Area, estimated using Bluebeam Revu set to scale of drawings = 113.58 sf

Width at primary abutment section = 24.8 ft.

Volume =  $113.58 \text{ sf} \times 24.8 \text{ ft} = 2817 \text{ cf} = 104 \text{ cy}$

South Concrete Barrier:

Cross Sectional Area = 0.75 ft width x 3.5 ft height = 2.625 sf

Calculate Length:  $\text{sqrt}(1.96'^2 + 15.79'^2) = 15.91 \text{ ft}$

Volume = 2.625 sf x 15.91 ft = 41.76 cf = 1.5 cy

East Concrete Overhang and Barrier:

Overhang Cross Sectional Area, estimated using Bluebeam = 5.93 sf

Barrier Cross Sectional Area = same as South Concrete Barrier = 2.625 sf

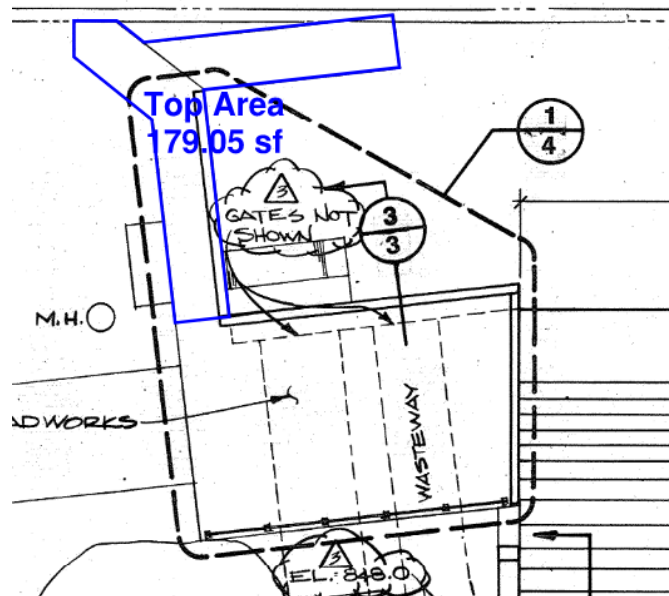

Length = 21'-10" = 21.83 ft

Volume = (5.93 sf + 2.625 sf) \* 21.83 ft = 186.76 cf / 27 = 6.9 cy

Total Right Abutment Volume with barriers = 572.6 + 104 + 1.5 + 6.9 = 685.0 cy

## Upstream Parapet Walls

Upstream Parapet Wall:

Top Area (estimated using Bluebeam Revu) = 179.05 sf

Depth of wall not given. Estimate = 15 ft

Volume = 179.05 sf x 15 ft = 2685.75 cf = 99.5 cy

Upstream parapet wall barrier:

Cross Sectional Area = 0.75 ft x 4.25 ft = 3.19 sf

Length = 17.5 ft

Volume = 3.19 sf x 17.5 ft = 55.83 cf = 2.1 cy

Total Parapet Wall Volume = 99.5 cy + 2.1 cy = 101.6 cy

### Outside Concrete Cross Sectional Area

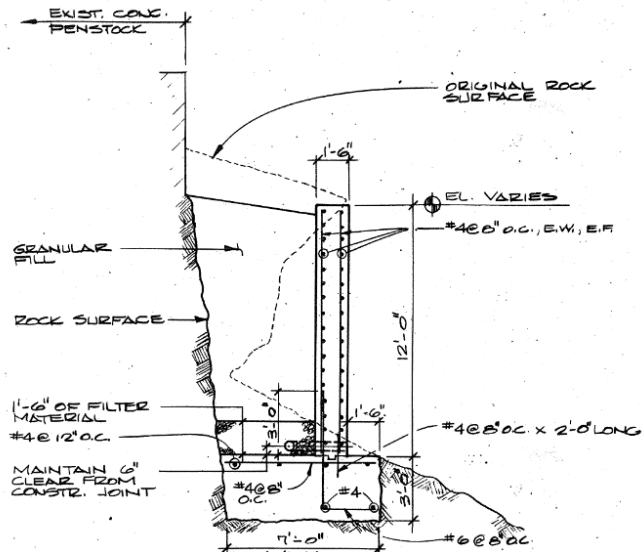

Inside Opening Cross Sectional Area: Inner diameter given as 5 ft.,  $A = \pi \times 2.5^2 = 19.63 \text{ sf}$

Net Concrete Cross Sectional Area = 57.92 ft – 19.63 ft = 38.29 sf

Length (roughly estimated from Bluebeam Revu): 21.5 ft + 77.67

$$\text{Volume} = 38.29 \text{ sf} \times 99.2 \text{ ft} = 3798.4 \text{ sf} / 27 = 140.7 \text{ cy}$$

## Right Retaining Wall

**SECTION RT. RETAINING WALL** 2  
3

Cross Sectional Area: Top = 1.5 ft x 12 ft = 18 sf

Bottom = 7 ft (minimum) x 3 ft = 21 sf

Length = given in plans = 50 ft

Volume = (18 sf + 21 sf) \* 50 ft = 1950 cf = 72.2 cy

## Powerhouse

Width of walls given as 2 ft (minimum)

Height of concrete portion of building given as 38.8 ft

Cross Sectional Area of walls =  $2 \times (16' \times 2') + 2 \times [(16' - 2' - 2') \times 2'] = 112 \text{ sf}$

Volume of walls (neglecting openings) =  $112 \text{ sf} \times 38.8 \text{ ft} = 4345.6 \text{ sf} = 160.9 \text{ cy}$

Outlet opening:

Calculate Cross Sectional Area with dimensions given in plans =  $(12.5' \times 12') - 2 \times (0.5 \times 2.5' \times 2.5') = 143.75 \text{ sf}$

Width = 2 ft

Volume of opening =  $143.75 \text{ sf} \times 2 \text{ ft} = 287.5 \text{ cf} = 10.6 \text{ cy}$

Penstock opening:

Given 5 ft diameter and 2 ft width

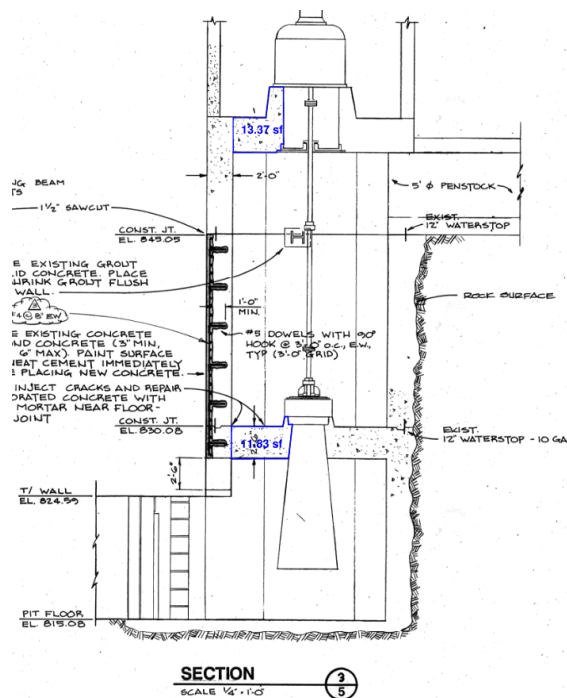

Volume =  $2 \text{ ft} \times (\pi \times 2.5'^2) = 39.26 \text{ cf} = 1.5 \text{ cy}$

Subtract openings from wall volume =  $160.9 \text{ cy} - 10.6 \text{ cy} - 1.5 \text{ cy} = 148.8 \text{ cy}$

Base Concrete Area:  $12 \text{ ft} \times 12 \text{ ft} = 144 \text{ sf}$

Assume 2 ft thickness

Base concrete volume =  $144 \text{ sf} \times 2 \text{ ft} = 288 \text{ cf} = 10.7 \text{ cy}$

Additional Powerhouse concrete:

Lower support cross sectional area (estimated using Bluebeam Revu):  $11.83 \text{ sf} \times 2 = 23.66 \text{ sf}$

Length =  $16 \text{ ft} - 2 \times (2 \text{ ft wall width}) = 12 \text{ ft}$

Volume =  $23.66 \text{ sf} \times 12 \text{ ft} = 283.92 \text{ cf} = 10.5 \text{ cy}$

Upper support cross sectional area (estimated using Bluebeam Revu):  $13.37 \text{ sf} \times 2 = 26.74 \text{ sf}$

Length =  $16 \text{ ft} - 2 \times (2 \text{ ft wall width}) = 12 \text{ ft}$

Volume =  $26.74 \text{ sf} \times 12 \text{ ft} = 320.88 \text{ cf} = 11.9 \text{ cy}$

Total additional powerhouse concrete =  $10.5 \text{ cy} + 11.9 \text{ cy} = 22.4 \text{ cy}$

Roof over top of masonry appears to be concrete:

Assume 1 ft thickness

Volume =  $16 \text{ ft} \times 16 \text{ ft} \times 1 \text{ ft} = 256 \text{ cf} / 27 = 9.5 \text{ cy}$

Total powerhouse concrete estimate =  $148.8 \text{ cy} + 10.7 \text{ cy} + 22.4 \text{ cy} + 9.5 \text{ cy} = 191.4 \text{ cy}$

### **Concrete Quantities Summary**

Spillway: 2192.1 cy

Left Abutment/Wingwall: 200.1 cy

Right Abutment: 685.0 cy

Upstream Parapet Walls: 101.6 cy

Penstock: 140.7 cy

Right Retaining Wall: 72.2 cy

Powerhouse: 191.4 cy

**Total Junction Falls Concrete Estimate = 3583.1 cy**

### **Rebar**

Reinforcement details for the existing concrete in the drawing set is not provided. Accordingly, a detailed rebar steel estimate cannot be made. An estimate of 2% rebar volume by concrete will be made. Assume A615 steel.

Rebar Volume Estimate:  $3583.1 \text{ cy} \times 2\% = 71.66 \text{ cy}$

A615 Steel Unit Weight:  $0.282 \text{ lb/in}^3 = 13157 \text{ lb/yd}^3$

Rebar Weight Estimate =  $71.66 \text{ cy} \times 13157 \text{ lb/yd}^3 = 942857 \text{ lbs.} = \underline{\underline{471 \text{ tons}}}$

## Masonry

### Powerhouse masonry estimate:

No dimensions given for top masonry portion of powerhouse

Assume 0.5 ft wall width, 10 ft height

16 ft x 16 ft dimensions

Cross Sectional Area of walls =  $2 * (16' \times 0.5') + 2 * [(16' - 0.5' - 0.5') \times 0.5'] = 31 \text{ sf}$

Volume of walls (neglecting windows) =  $31 \text{ sf} * 10 \text{ ft} = 310 \text{ cf} = 11.5 \text{ cy}$

Assume cross sectional area of windows =  $1.5 \text{ ft} \times 2.5 \text{ ft} = 3.75 \text{ sf}$

Volume =  $3.75 \text{ sf} \times 0.5 \text{ ft} \times 4 \text{ windows} = 7.5 \text{ sf} = 0.3 \text{ cy}$

Subtract wall openings:

Volume of walls =  $11.5 \text{ cy} - 0.3 \text{ cy} = 11.2 \text{ cy}$

### Additional river-level masonry structure (river-level):

The additional masonry structure located roughly river-level is not found in the drawings. The quantity of masonry for this structure was conservatively estimated to be 75% of the quantity for the powerhouse masonry section.

Additional masonry structure estimate:  $75\% \times 11.2 \text{ cy} = 8.4 \text{ cy}$

**Total Masonry Estimate =  $11.2 \text{ cy} + 8.4 \text{ cy} = \underline{19.6 \text{ cy}}$**

Aquatic Ecosystem Restoration and Protection  
Project

**Powell Falls Concrete Quantity Estimate**

**Spillway**

### Spillway Section A:

Cross Sectional Area (estimated using Bluebeam Revu): 247.85 sf

Length (taken from plans):  $4.5+8+9.2+8.7+9+7.8+8+8+8 = 71.2$  ft

Volume =  $247.85 \text{ sf} \times 71.2 \text{ ft} = 17646.92 \text{ sf} = 653.6 \text{ cy}$

### Spillway Section B:

Cross Sectional Area (estimated using Bluebeam Revu): 223.54 sf

Length (taken from plans):  $8+8+8+8+5 = 37$  ft.

Volume =  $37 \text{ ft} \times 223.54 \text{ sf} = 8270.98 = 306.3 \text{ cy}$

### Right Main Spillway Abutment/Wingwall:

Width given as 2.5 ft. No other values given. Conservatively assume rectangular section with same height and width as main spillway, section A.

Height = 16.5 ft.

Length = 26.75 ft

Volume =  $2.5 \text{ ft} \times 16.5 \text{ ft} \times 26.75 \text{ ft} = 1103.4 \text{ cf} = 40.9 \text{ cy}$

### Left Main Spillway Abutment:

Top Area derived from drawings using Bluebeam Revu: 25.72 sf

Assume rectangular cross section with same height as main spillway, section B.

Height = 12.5 ft

Volume =  $25.72 \text{ sf} \times 12.5 \text{ ft} = 321.5 \text{ cf} = 11.9 \text{ cy}$

### Concrete Total for Main Spillway and Abutments/Wingwalls:

Main Spillway Section A: 653.6 cy

Main Spillway Section B: 306.3 cy

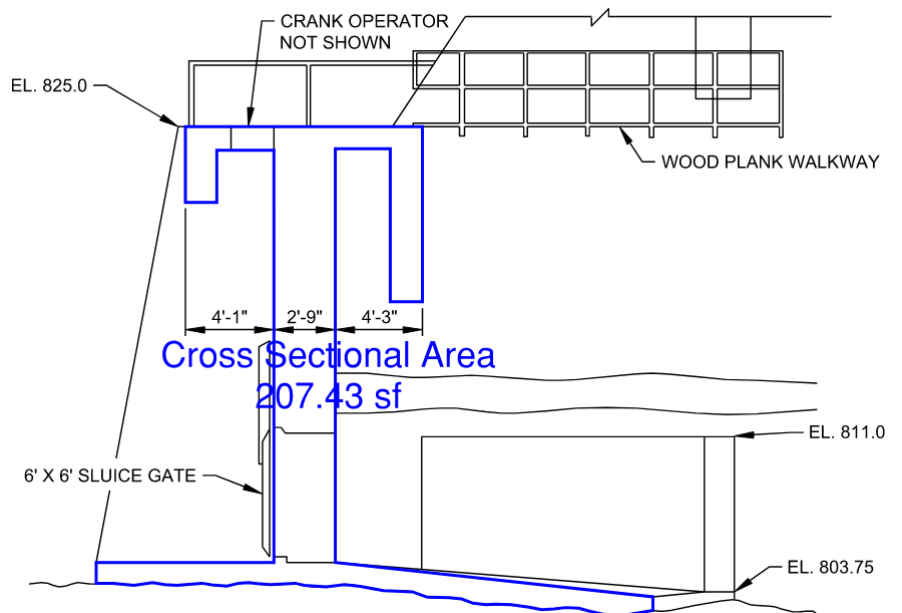

Right Spillway Abutment/Wingwall: 40.9 cy

Left Spillway Abutment: 11.9 cy

**Total: 1012.7 cy**

### Wasteway and Intake Bay

Wasteway face, walkway, and apron:

Total Cross-Sectional Area (estimated using Bluebeam Revu): 207.43 sf

Subtract gate opening and crank opening:  $207.43 \text{ sf} - 33.1 \text{ sf} - 4.21 \text{ sf} = 170.12 \text{ sf}$

Length of wasteway given in plans as 12 ft.

Volume =  $170.12 \text{ sf} \times 12 \text{ ft} = 2041.44 \text{ cf} = 75.6 \text{ cy}$

Right Downstream Wasteway Wingwall:

Section A:

Top section area estimated using Bluebeam Revu: 6.48 sf

Conservatively assume rectangular cross section extending from wasteway elevation values of 803.75 to 825.0.

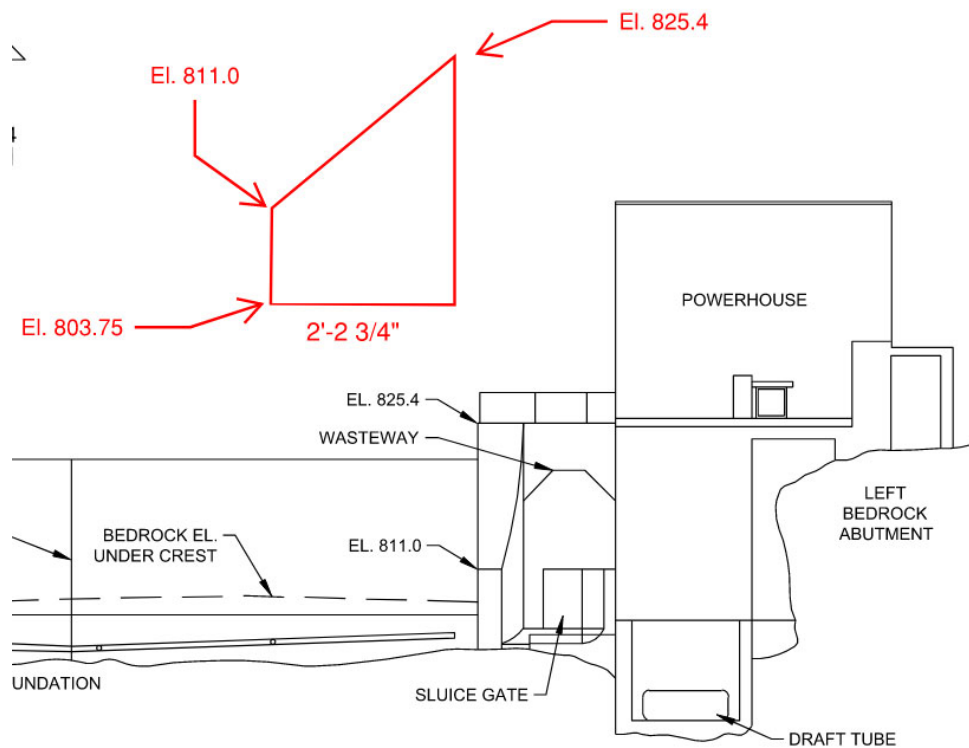

Height =  $825.0 - 803.75 = 21.25 \text{ ft}$

Volume =  $6.48 \text{ sf} \times 21.25 \text{ ft} = 137.7 \text{ cf} = 5.1 \text{ cy}$

## Section B

A rough side cross section was derived using an estimated length (2.23 ft) and the elevation values provided.

Cross Section Area:  $[(811.0 - 803.75) \times 2.23] + \frac{1}{2} \times [2.23 \times (825.4 - 811.0)] = 16.1675 = 32.22 \text{ sf}$

Estimate average width as 2 ft.

Volume =  $32.22 \text{ sf} \times 2 \text{ ft} = 64.4 \text{ cf} = 2.4 \text{ cy}$

Total Right Wingwall Volume =  $5.1 \text{ cy} + 2.4 \text{ cy} = 7.5 \text{ cy}$

Left Downstream Wasteway Wingwall:

Top section estimated using Bluebeam Revu: 8.52 sf

Conservatively assume rectangular cross section extending from El 803.75 to El 811.0

Height =  $811.0 - 803.75 = 7.25 \text{ ft}$

Volume =  $8.52 \text{ sf} \times 7.25 \text{ ft} = 61.77 \text{ cf} = 2.3 \text{ cy}$

Upstream Wasteway Wingwall

Not shown on plans. Roughly outlined on photo below.

Estimated from photos to be 75% of the volume of the downstream right wasteway wingwall.  
 Estimated volume:  $75\% \times 7.5 \text{ cy} = 5.6 \text{ cy}$

Pier between Wasteway and Intake Bay

Top area estimate using Bluebeam Revu: 29.14 sf

Assume rectangular cross section. Height estimated using Bluebeam Revu: 10'-2" = 10.17 ft  
 Volume = 29.14 sf x 10.17 ft = 296.35 cf = 11.0 cy

#### Left Pier of Intake Bay

Top area estimated using Bluebeam Revu: 7.89 sf  
 Assume same height as intermediate pier: 10.17 ft.  
 Volume = 7.89 sf x 10.17 ft = 80.24 cf = 3.0 cy

## Intake Bay Faces, Walkway, and Apron

Total cross sectional area estimate using Bluebeam Revu: 29.13 sf + 7.09 sf + 39.07 sf + 45.27 sf = 120.56 sf

All of this cross section is assumed to run the given 12'-8" (12.75 ft) given width of the intake bay.

Volume = 120.56 sf x 12.75 ft = 1537.14 = 56.9 cy

Tailrace:

Cross sectional area estimated using Bluebeam Revu: 35.38 sf

Assume tailrace extends from El. 796.26 to El. 806.09

Height:  $806.09 - 796.29 = 9.8$  ft.

Volume Estimate:  $35.38 \text{ sf} \times 9.8 \text{ ft} = 346.72 \text{ cf} = 12.8 \text{ cy}$

**Total wasteway/intake bay and tailrace concrete:**

Wasteway face, walkway, and apron: 75.6 cy

Right downstream wasteway wingwall: 7.5 cy

Left downstream wasteway wingwall: 2.3 cy

Upstream wasteway wingwall: 5.6 cy  
Pier between Wasteway and Intake Bay: 11.0 cy  
Left pier of Intake Bay: 3.0 cy  
Intake Bay Faces, Walkway, and Apron: 59.9 cy  
Tailrace: 12.8 cy  
**Total: 177.7 cy**

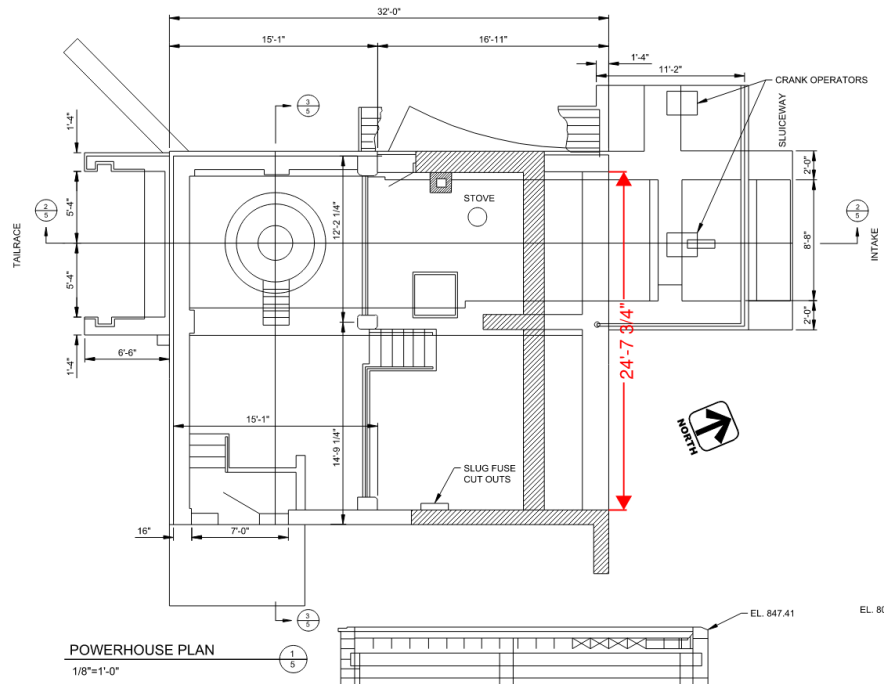

### **Powerhouse:**

Note that roofs/ceilings are assumed to be composed of miscellaneous wood and steel members.

### **Upstream Side of Powerhouse**

Floor and North Wall

Floor and north wall cross section estimated using Bluebeam Revu: 32.67 sf

Length of wall and floor: 24'-7 3/4" = 24.65 ft.

Volume = 32.67 sf x 24.65 ft = 805.32 cf = 29.8 cy

East and West Walls and North Wall Support:

Top Section area estimated using Bluebeam Revu: 25.64 sf + 7.9 sf + 21.63 sf = 55.16 sf

Extend from Elevation values given in Powerhouse Generator cross section: El. 825.4 to El. 837.10 = 11.7 ft

Volume = 55.16 sf x 11.7 ft = 645.37 cf = 23.9 cy

## Downstream Side of Powerhouse

*North and South Walls:*

Cross sectional area estimated using bluebeam Revu:  $23.74 \text{ sf} + 11.47 \text{ sf} = 35.21 \text{ sf}$

Assume same length as upstream north wall:  $24'-7 \frac{3}{4}" = 24.65 \text{ ft.}$

Gross Volume:  $35.21 \text{ sf} \times 24.65 \text{ ft} = 867.93 \text{ cf} = 32.1 \text{ cy}$

Subtract Windows (now boarded up)

Area estimated using Bluebeam Revu:  $25.78 \text{ sf} \times 2 \text{ windows} = 51.56 \text{ sf}$

Assume 12" concrete blocks as called out for the south wall in the section view.

Volume:  $51.56 \text{ sf} \times 1 \text{ ft} = 51.56 \text{ cf} = 1.9 \text{ cy}$

North and South Walls Net Volume:  $32.1 \text{ cy} - 1.9 \text{ cy} = 30.2 \text{ cy}$

East and West Walls:

Cross sectional area estimated using Bluebeam Revu: 22.07 sf + 17.81 sf = 39.88 sf

Length provided in plan view: 15'-1" = 15.08 ft.

Volume: 39.88 sf x 15.08 ft. = 601.39 cf = 22.3 cy

Total gross volume of upstream side walls: 22.3 + 30.2 = 52.5 cy

Note that the columns and some of the surrounding material on the upstream half of the building is comprised of masonry bricks rather than concrete bricks. This masonry volume needs to be calculated and subtracted from the wall concrete quantities.

Note that the brick appears to extend up to the elevation of the top of the windows.

The top of the windows was estimated using Bluebeam Revu to be at El. 842.56

Using a bottom Elevation value of 825.86, the height of the masonry column sections was estimated:  
 $842.56 - 825.86 = 16.7 \text{ ft.}$

Cross sectional area of columns estimated using Bluebeam Revu: 3.33 sf + 3.04 sf + 1.88 sf + 2.84 sf + 1.45 sf + 2.56 sf = 15.1 sf

However, some of the material surrounding the columns also appears to be masonry bricks. To account for this, the cross-sectional area is to be increased (conservatively) by 50%

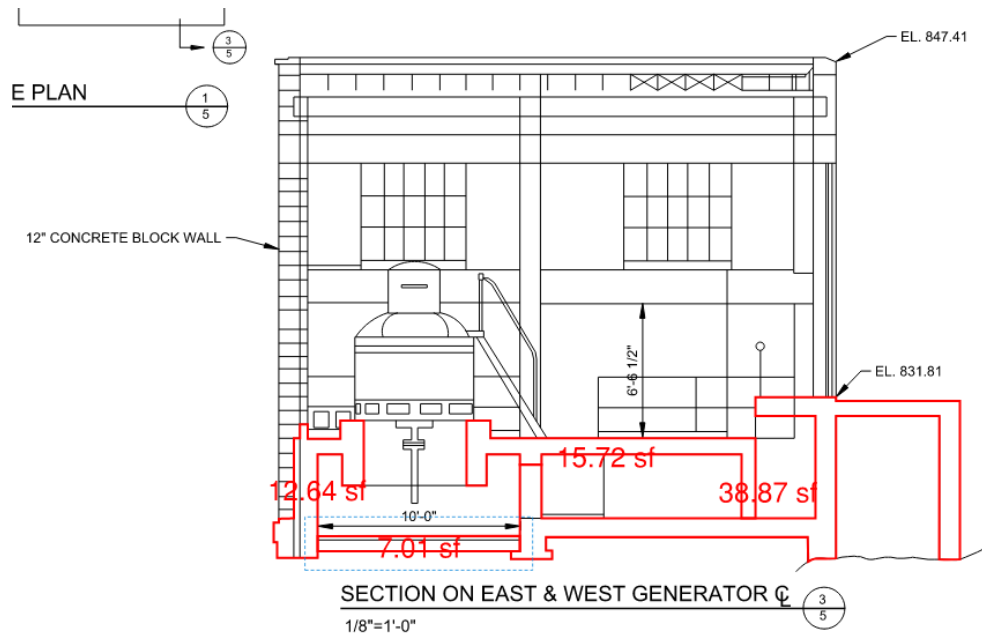

Cross Sectional Area: 15.1 sf \* 150% = 22.65 sf

**Estimated Masonry Volume: 22.65 sf x 16.7 ft = 378.26 cf = 14.0 cy**

Estimated net volume of downstream concrete walls = 52.5 cy - 14.0 cy = 38.5 cy

### Concrete Floors

Section area of upstream concrete floors and outcropping estimated using Bluebeam Revu: 12.64 sf + 7.01 sf + 15.72 sf + 38.87 sf = 74.24 sf (*Note that this is a very conservative estimate*)

Length of upstream side, given in plan view: 15'-1" = 15.08 ft.

Estimated Volume: 74.24 sf x 15.08 ft. = 1119.54 cf = 41.5 cy

### Total Powerhouse Concrete:

Upstream floor and north wall: 29.8 cy

Upstream east and west walls and north wall support: 23.9 cy

Downstream walls: 38.5 cy

Downstream Floors: 41.5 cy

**Total: 133.7 cy**

#### Miscellaneous Additional Structures:

The abutment/retaining wall on the east side of the intake bay is not accounted for in the drawings. The length and thickness of this wall is not known, and sufficient photos are not available to make a proper estimate. To account for this structure and possible additional concrete features such as retaining walls not shown in the available drawings, an additional 30 cubic yards will be added to the concrete estimate.

#### **Concrete Quantities Summary**

Main Spillway and Abutments/Wingwalls: 1012.7 cy

Wasteway, Intake Bay, and Tailrace: 177.7 cy

Powerhouse: 133.7 cy

Miscellaneous Additional Concrete: 30 cy

**Total Concrete Estimate: 1354.1 cy**

#### **Rebar**

Most rebar details are not provided in the drawings. An estimate of 2% rebar by concrete volume will be made.

Rebar Volume Estimate:  $1354.1 \text{ cy} \times 2\% = 27.1 \text{ cy}$

A615 Steel Unit Weight:  $0.282 \text{ lb/in}^3 = 13157 \text{ lb/yd}^3$

Rebar Weight Estimate =  $27.1 \text{ cy} \times 13157 \text{ lb/yd}^3 = 359555 \text{ lbs.} = \mathbf{178 \text{ tons}}$

**Masonry**

(Previously calculated)

Unless otherwise specified, the blows per foot at the locations indicated are based on driving a 2" O. D. x 1.4" I. D. split spoon sampler with a 140° hammer having a free fall of 30". The blow count is taken in undisturbed soil immediately below a cased or open hole eliminating side friction on the drive pipe.

SUBSURFACE EXPLORATION FOR FOUNDATION DESIGN AND BIDDERS INFORMATION

To obtain relative data concerning the character of material in and upon which the foundation might be built, borings and/or soundings were made at points approximately as indicated on this drawing. The data presented herein represents the findings of the subsurface explorations made. However, because the depths investigated are limited and the area of the borings and/or soundings is very small in relation to the entire area, the Division of Highways does not warrant conditions below the depths investigated or that the classification of material encountered in these investigations is necessarily typical of the entire site.

- NOTES:
- 1 DRIVEN STEEL POSTS, PIPES, OR CHANNELS. LENGTH SHALL BE SUFFICIENT TO SECURELY SUPPORT BARRIER AT HIGH WATER ELEVATIONS.
  - 2 SAND BAGS TO BE USED AS ADDITIONAL BALLAST WHEN ORDERED BY THE ENGINEER TO MEET ADVERSE FIELD CONDITIONS.
  - 3 WHEN BARRIER HEIGHT, H, EXCEEDS 8'-0" POST SPACING MAY NEED TO BE DECREASED.
  - 4 ELEVATION VALUE TO BE ESTABLISHED BY THE CONTRACTOR BASED ON THE TIME OF YEAR AND DURATION OF THE ACTIVITY.
  - 5 TURBIDITY BARRIER SHALL COMPLETELY ENCLOSE ACTIVE DREDGING AREA AND BREAKWATER CONSTRUCTION AREA. CONTRACTOR SHALL DETERMINE LENGTH OF TURBIDITY BARRIER REQUIRED FOR CONTRACTORS OPERATION.

1 **TURBIDITY BARRIER DETAIL**  
N.T.S. 0156203

GENERAL NOTES:

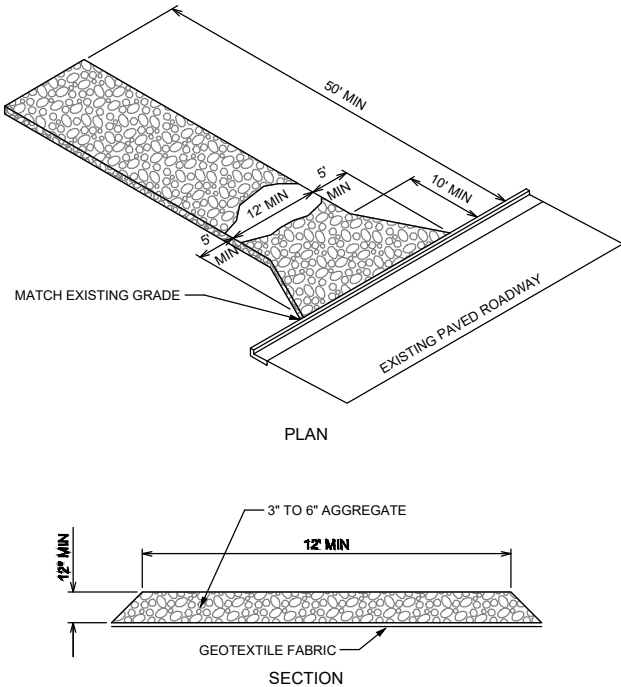

- 1 TRENCH SHALL BE A MIN OF 4" WIDE & 6" DEEP TO BURY AND ANCHOR THE GEOTEXTILE FABRIC, FOLD THE MATERIAL TO FIT TRENCH AND BACKFILL & COMPACT TRENCH WITH EXCAVATED SOIL.
- 2 WOOD POSTS SHALL BE A MIN SIZE OF 1 1/2" x 1 1/2" OAK OR HICKORY.
- 3 CONSTRUCT SILT FENCE FROM A CONTINUOUS ROLL IF POSSIBLE BY CUTTING LENGTHS TO AVOID JOINTS. IF A JOINT IS NECESSARY, USE ONE OF THE FOLLOWING TWO METHODS:
  - A. TWIST METHOD - OVERLAP THE END POSTS AND TWIST, OR ROTATE, AT LEAST 180 DEGREES.
  - B. HOOK METHOD - HOOK THE END OF EACH SILT FENCE LENGTH.

2 **SILT FENCE DETAIL**  
0156201

3 **JOINING 2 LENGTHS OF SILT FENCE**

3 **STONE TRACKING PAD**  
0156201

4 **EROSION MAT INSTALLATION DETAIL**

5 **TEMPORARY SETTLING BASIN**

LOCATE TEMPORARY SETTLING BASIN ON LEVEL OR GENTLY SLOPED TERRAIN. WHERE FEASIBLE, LOCATE BASIN OUTFALL SO THAT DISCHARGED WATER DIRECTLY ENTERS EITHER A VEGETATED AREA OR THE WATERWAY SO THAT EFFLUENT HAS MINIMAL OPPORTUNITY TO ENTRAIN SUSPENDED SOLIDS AFTER THE SETTLING POND.

(SIZE TO BE DETERMINED IN FIELD AS INDICATED BELOW:)

STORAGE VOLUME (SV in C.F.) = 16 X GPM (PUMP RATE)

EXAMPLE:  
CONTRACTOR INDICATES PUMP CAPABLE OF 50 GPM  
HEIGHT OF BALES = 1.5 FT.

SOLUTION:  
SV in C.F. = 16 X 50  
SV = 800 C.F.  
 $\frac{800 \text{ C.F.}}{1.5 \text{ FT.}} = 533 \text{ S.F.}$   
USE A 20 FT. X 27 FT. BASIN

(CAP) Detailed Project Report  
Kinnickinnic River  
Aquatic Ecosystem Restoration and Protection  
Project

## 4. Dam Removal

Removing Junction and Powell Falls Dams requires planning how the structures will be removed, including access to the dams, demolition and disposal, and how to manage the water during the project. The following methods and approaches recommended for tearing down the dams are based on preliminary information and have not been engineered to final design or approved by any municipal or other government entity. Final design recommendations may differ, and construction contractors often have novel approaches to improve efficiencies and reduce costs.

This report assumes a project involving removal of both dams concurrently or in immediate succession. It is assumed that the same sediment management approach will be used for both dams, or that the sediment management approach will be fully coordinated between the two dam removals.

### 4.1 STAGING AND ACCESS PLAN

*Junction Falls Access* - Junction Falls Dam is accessible at the top of the right abutment via City property and the area below the dam can be accessed along the gated access road from Glen Park (Figure 21). Materials and equipment can be moved along the latter access path, and it can be locked during off hours. Utilizing this proposed access route will require the following steps:

1. Improvements to the existing paved trail to allow vehicle clearance.
2. Addition of gravel construction access pad at the end of the pavement. The gravel pad would likely be built to a height that avoids impacts from moderately high flows. Exact elevation would be determined during final design.
3. Construction of a river crossing at the South Fork Kinnickinnic River. This crossing will need to include culverts to convey South Fork Kinnickinnic River flow and would likely be constructed of a cobble base and a gravel road base. Culvert sizing would be accomplished during final design.
4. Improved construction access up Junction Falls to a work pad to be used for demolition work. The South Fork road can transition to a ramp that brings equipment to the flat area below the spillway. A gravel pad can be installed to protect the bedrock from damage.
5. Staging for both Junction Falls Dam demolition and the upper Lake Louise restoration activity can be located both at the top of the incline road within Park entrance (e.g. parking lot, construction trailer), and at the bottom of the incline in the floodplain on river left (e.g., active equipment storage, parking). Weather can be monitored and equipment moved to higher ground as needed.
6. Upon finishing construction, the temporary construction ramp and road would be removed.
7. Signs and fencing should be posted at entrances to warn residents to keep out of the construction area.

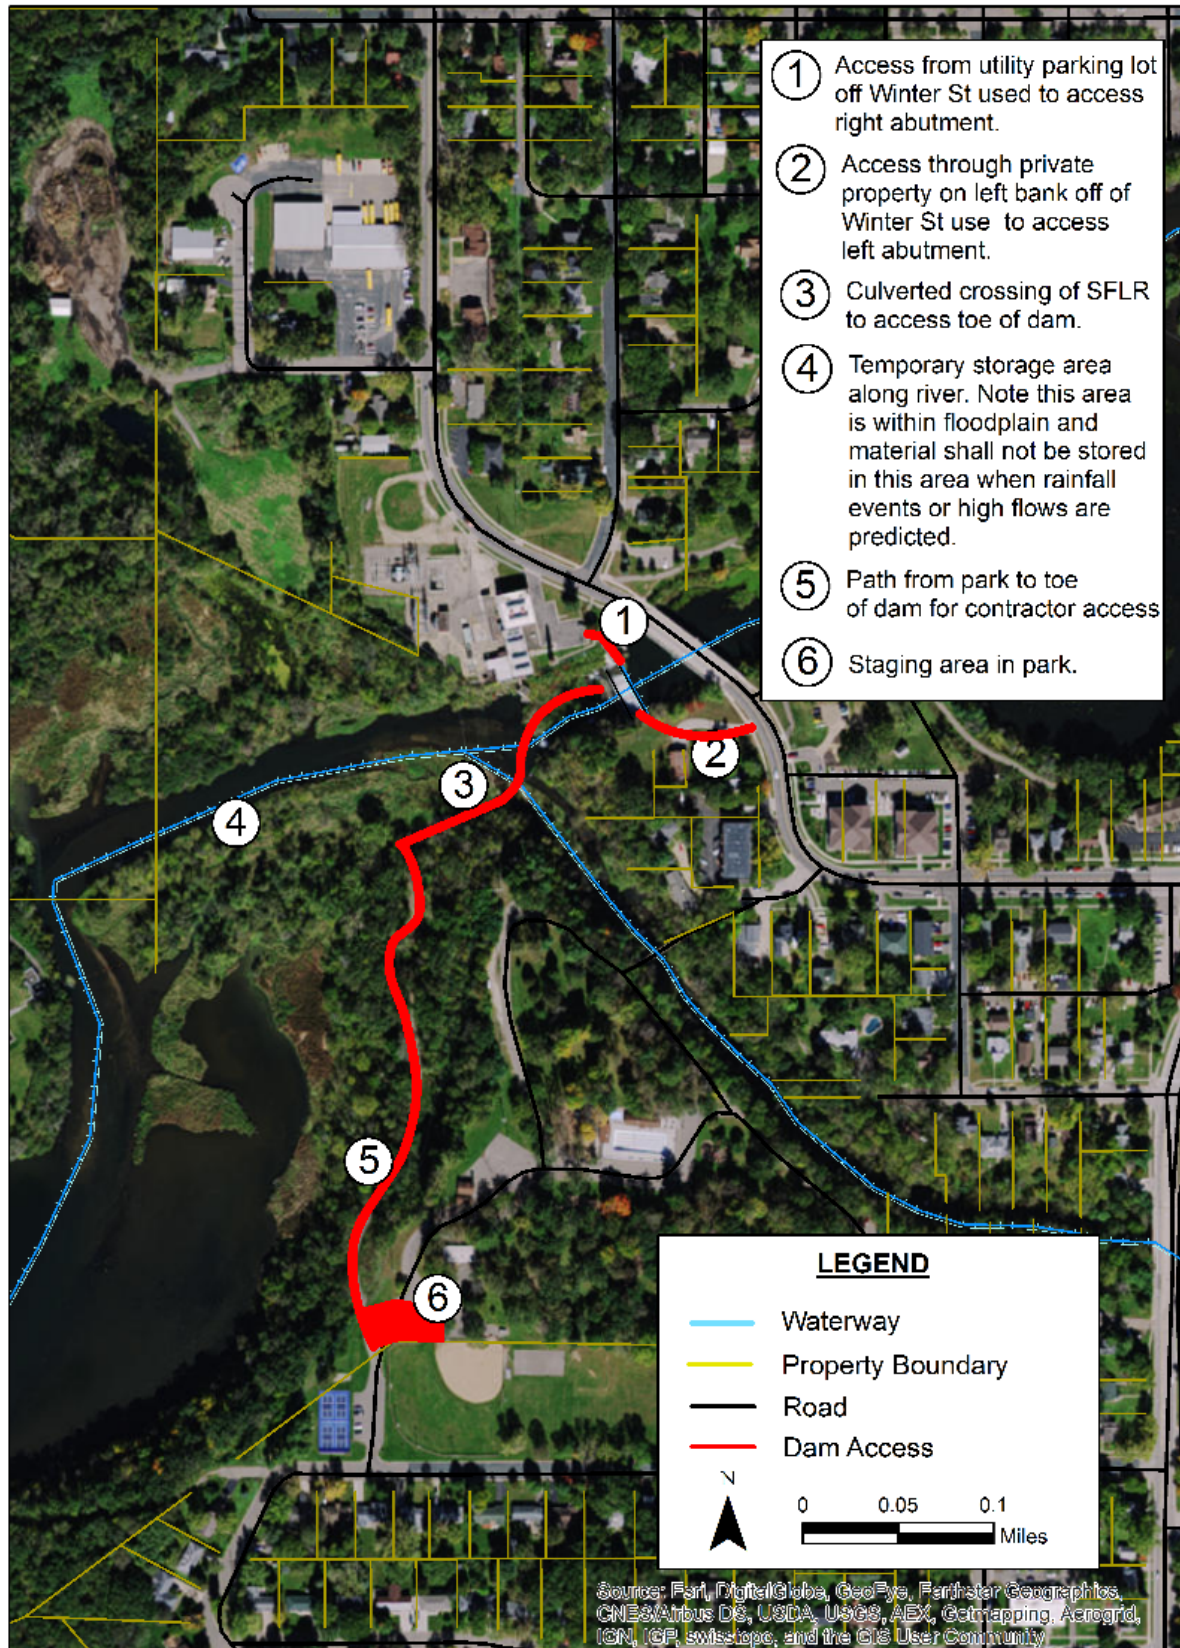

Figure 21: Junction Falls – Proposed Access Plan

Additional access may be accomplished from the top of the gorge wall on either the right or left bank. Right bank access would be on public property and left bank access would be through private property (including residence) at 407 South Winter Street.

The following access routes were considered, but deemed infeasible:

- Access from upstream of the dam via barge. This action was considered to be problematic due to clearance and size issues at the Winter Street Bridge. A barge may be able to navigate the river above Junction Falls Dam, but it may not fit between the bridge piers or under the bridge beams (with or without an excavator).
- Access via haul road from left bank of the gorge upstream of the dam.

Access to the Lake George impoundment area can be gained through either side of Winter Street Bridge. The East side of the bridge has an old mill access road on river left, while the existing walk path and parking area on right bank could be used as the main right floodplain entrance location. Temporary haul roads may need to be constructed as the sediment dries out upon drawdown.

*Powell Falls Access* - Access at Powell Falls is also targeted at the downstream side of the spillway. Haul trucks typically need an incline of less than 10% for effective and safe hauling, but the steep valley walls near the dam exceed 10% slope. Therefore, the most practical route to the base of the dam is the South Kinnickinnic River Trail, which connects Powell Dam to the intersection of Bartosh Lane and Foster Street on river right. The upper part of the left abutment can be accessed via a constructed paved or gravel path through Glen Park and the toe of the dam can be accessed via the South Kinnickinnic River Trail. Figure 22 shows the proposed access route for Powell Dam.

Steps for accessing the toe of the dam for demolition will follow these steps:

1. Improvements to the South Kinnickinnic River Trail to allow for vehicle clearance.
2. Add a gravel construction access to local road connections to limit turf and concrete damage and control erosion.
3. Construct a gravel access path along the left side of the river, possibly as far as 10 feet out into the channel margin. Elevations will need to be determined during final design to meet permit requirements and protect equipment.
4. Construct a crossing at the Bartosh Lane wastewater outlet, avoid damaging the newly installed stormwater outlet.
5. Improve construction access to the toe of Powell Falls Dam through construction of a work pad at the base of the dam.
6. Staging areas could be at the top of the path or in Glen Park. The southwest end of Glen Park offers a central staging area for both projects, thereby minimizing costs for mobilization and staging.

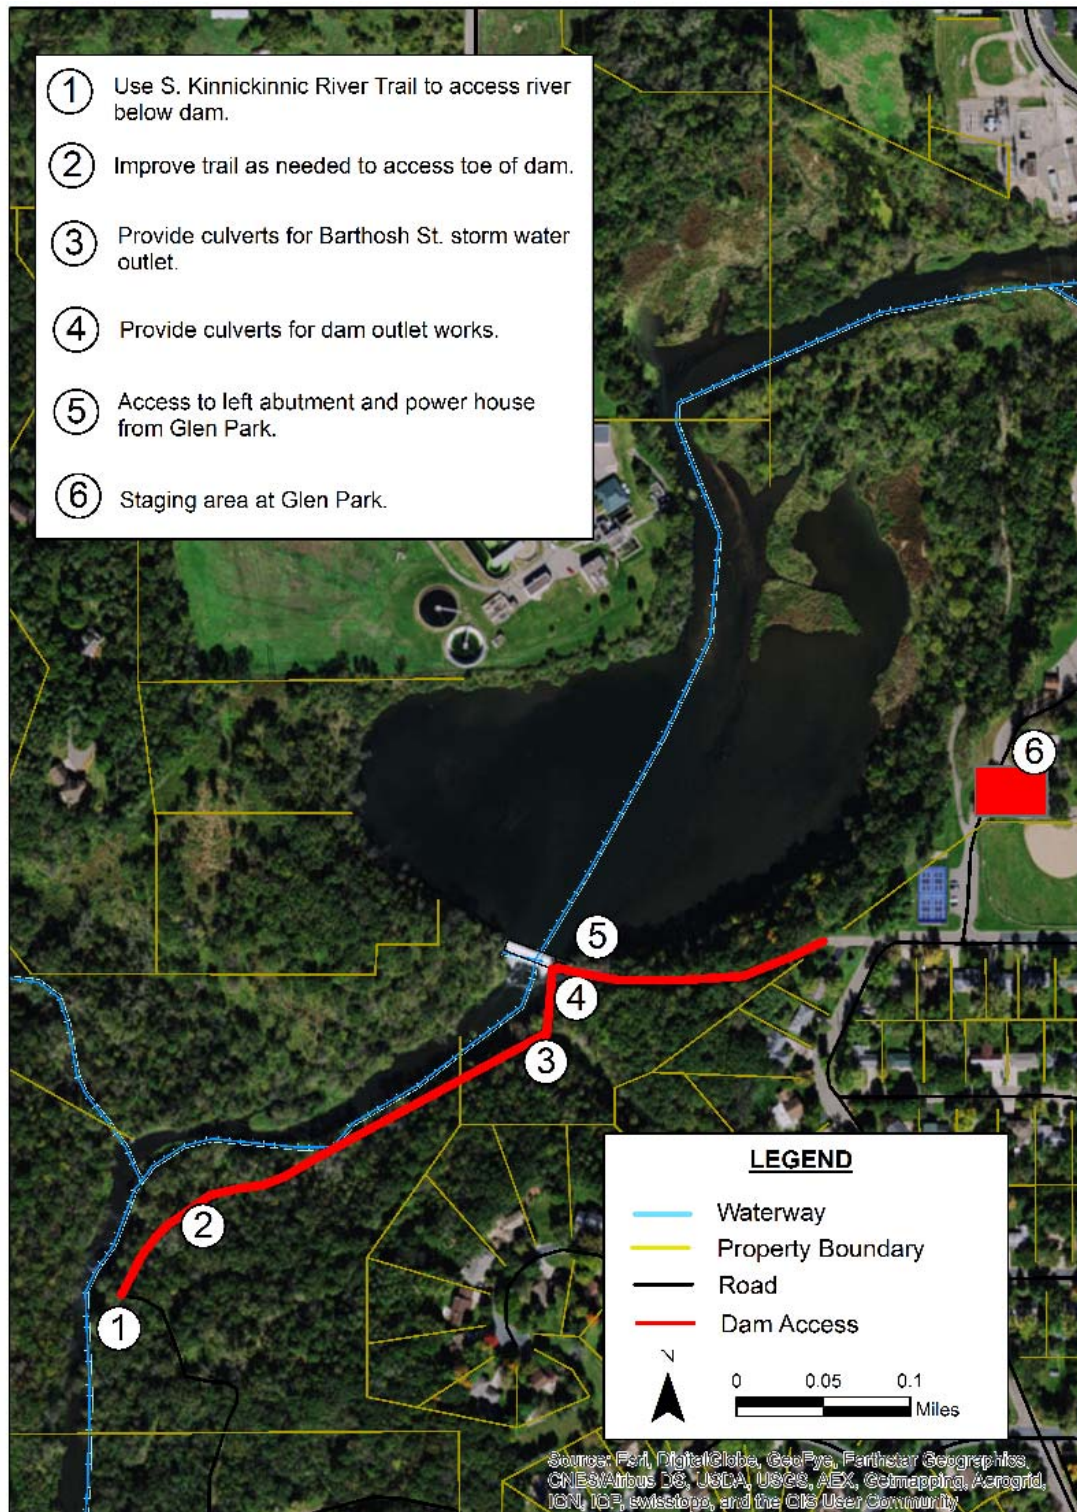

Figure 22: Powell Falls – Proposed Access Plan

## 4.2 PRELIMINARY DEMOLITION AND DEBRIS DISPOSAL PLAN

Demolition of the dams should begin once the impoundment water levels have been reduced using the wasteway bypass gates. The sequencing of removal should be determined during final design and with contractor input as staging area and equipment may play a role into the precise approach. However, in general, the demolition should proceed with the following concepts:

- Water flow through the wasteway gate and other temporary means of conveyance used during construction must be uninterrupted. Initial drawdown should minimize sediment transport in the impoundment areas. This can include managed output rates.
- Dam spillway notching from below the dam, starting at the top of the spillway and working down using either sawcut equipment or a hydraulic hammer mounted to a track excavator.
- Removed material will be transported away from the site via the construction access.
- The dam structures will need to be removed in a controlled fashion so that water flow is not interrupted and fine concrete debris washing into the river is minimized.
- Waste material will need to be removed on a continuous basis and should not be stored in the floodplain.

Traditionally, the “means and methods” for demolition are left to the contractor, however, for these cost estimates, it is assumed that the contractor will use a hydraulic hammer attached to an excavator to demolish the dam (Figure 23). Demolition rates can be relatively slow using this technique, depending on the density of steel reinforcement or the type of equipment used. Inter-Fluve recommends notching the spillway in 4 to 5 foot increments before hammering deeper on the dam face. This method allows for closing the gates if needed, but at a lower upstream pool volume to manage sediment excavation in the impoundment. Sediment immediately upstream of the spillway will likely need to be excavated to facilitate work. Once sections are demolished, hydraulic excavators and/or front end loaders will be required at the downstream base of the dam to load the debris onto trucks. The contractor may be required to salvage the reinforcing steel for recycling or disposal. Disposal can involve simple bulk loading of concrete and rebar, or secondary staging piles, divided into concrete and stripped rebar, can be generated prior to loading. Rebar can be partially stripped of concrete by having the jackhammer comb through the rebar and remove concrete. Additionally, vibration monitoring should be conducted to protect nearby buildings and other infrastructure such as Winter Street Bridge and the historic smoke stack on city property.

It may be feasible to leave the abutments intact if removing them causes the project to exceed available funds or if their removal would have a potential impact on nearby infrastructure. If this is a desired endpoint, a structural analysis of the portions of the dam that may be left would be required to verify that they are not under threat of collapse.

In lieu of a hydraulic hammer, saw cutting using a diamond wire saw is well-suited to demolishing sections of the reinforced concrete spillway and abutments. The saw consists of a hydraulic/electric drive unit and a series of pulleys designed to apply tension to and guide the diamond wire. The wires are then threaded through drilled holes and pulled in the direction of the cut as they circulate. The pulleys, guides, and wire are relatively light and can be set up by hand or lifted into place by a

small machine. This method is more expensive, but limits the harmful vibrations, noise, debris, and dust associated with hammering. Holes would be drilled at the corners of the cut area in order to insert the saw bands. The diamond wire saw band is then threaded through the holes and attached to the saw. The cuts create well-defined sections, or blocks, of concrete. A crane would be required to remove and load the cut sections onto trucks.

Multiple demolition methods can be combined to complete the project. Hammering is the most efficient way to breach the spillway. However, the clean cuts of the diamond wire saw are likely preferred to demolish sections surrounding essential infrastructure. Finally, the inability to control debris, and the impact of the noise and possible shaking to the adjacent urban area, prohibits blasting as a removal method.

Demolition of Junction Falls and Powell Falls Dams will require extensive concrete removal, and may require removing the penstock and adjacent concrete and brick structures to fully expose the bedrock. Salvage and protection of any of these adjacent structures will be coordinated during the final design process. The location, dimension, and orientation of demolished spillway and abutment sections should be planned out so that the remaining portions of the dam are stable for anticipated loads. Concrete adhering directly to bedrock wall areas will require fine excavation, handwork or sandblasting.

Measurements taken from the 1990 dam reinforcement design plans suggest demolition of Junction Falls Dam will generate 1800 cubic yards of reinforced concrete including the removal of the penstock. At Powell Falls Dam, photograph and design plans suggest removal will generate an estimated 942 cubic yards of reinforced concrete.

Reinforced concrete removal quantities assume both spillways are comprised of solid concrete. The removal of the two powerhouses may also be demolished and removed pending City input and the outcome of a recommended Phase 1 investigation. Due to the likelihood that asbestos and PCB material is present at the two powerhouses, required handling and disposal requirements for these and other materials, governed by state statutes, may be defined in a Phase 1 investigation.

To minimize construction traffic through River Falls, it will be advantageous to locate off-site debris and sediment disposal sites south of the City. The preferred hauling route for sediment and demolition debris, such as concrete, rebar and other solid waste, will be via the inclined access road, Park Street, and southbound South Main Street. For northbound traffic, 830<sup>th</sup> Avenue can be used to access Hwy 65 north. Access for sediment removal and restoration of the Lake George

**Figure 23. Jackhammers comb through a rebar reinforced concrete spillway during dam demolition (photo Inter-Fluve).**

impoundment can be via the old mill ramp on the east side of the river north of Winter Street, or from the park trail parking lot area on the west side of the river north of Winter Street. Truck traffic would be routed to South Main Street or 830<sup>th</sup> Avenue. Hauling of all removed concrete would require between 140 and 200 truckloads, depending on the haul volume per truck.

### 4.3 PRELIMINARY WATER ROUTING PLAN

#### 4.3.1 Dewatering Methods

Dewatering of the impoundments (Lake Louise and Lake George) will benefit from the inclusion of a lake drain in the design of the structures. This component of the dams is referred to as the wasteway on the existing dam plans. At Junction Falls Dam, this outlet is controlled by a gate and the operator indicated that the gate is operable and has been used in the past for maintenance purposes. At the Powell Falls Dam, the wasteway gate is also operable by a controlling gate. However, the gate is aged and appears to not have been operated recently. The operator speculated that the gate could be opened but not closed.

Due to the presence of the wasteway openings, the dewatering approach can follow these general steps:

1. Lower the water to the minimum level possible using main opening to tailrace.
2. Clean any debris from screens and remove accumulated material from in front of the wasteway gate.
3. Open the wasteway gate in a controlled fashion to comply with drawdown permit requirements (typically 1' or less per day or customized for notching and sediment management).
4. Install a debris boom in front of the wasteway opening to avoid clogging during dam demolition.
5. Remove the primary spillway in stages. Coordinate with sediment management upstream.
6. Install a cofferdam or other water control if needed (e.g. Supersacks or other means) to isolate the left abutment for removal in the dry or partial wet.
7. Remove the left abutment. Repeat for the right abutment.
8. Remove the cofferdam and construction access roads.

This approach will require heavy equipment to cross flowing water at the base of each dam to reach the right abutment. Alternatively, the contractor could remove the right abutment from the top of bank to avoid an additional cofferdam and river crossing.

Other considerations:

- Work should be scheduled for low flow periods, typically between July and February.
- Work must consider local haul road restrictions.
- The impoundment drawdown should be limited to a maximum of 1 foot per day or less. However, this assumption should be verified by a geotechnical investigation and through coordination with sediment management practices upstream.

- Sediment management activities need to be coordinated with drawdown activities to limit sediment mobilization beyond permitted levels. Sediment traps may need to be installed downstream of Powell Falls Dam and need to be designed with the haul/access road in mind.
- A Staged drawdown is typically the best way to lower impoundment levels for sediment removal and restoration. The drawdown can be done by opening gates incrementally.
- Fisheries restrictions may apply to the drawdown, and could limit work in the Fall and Winter due to the potential for trout spawning. However, since these reaches are not healthy trout waters, a variance may be appropriate. The WDNR ERR report (2016) recommends a spring/summer drawdown to protect overwintering herptiles.
- Work periods should be limited to daylight hours and possibly early evening hours to limit noise impacts. Such limits can be coordinated with stakeholders.

Alternative dewatering approaches that could be considered if the wasteway gates do not operate or the wasteway channel is otherwise inoperable include:

- It is possible for a contractor to remove sections of the dam using an excavator-mounted hydraulic hammer while water is flowing over the primary spillway (i.e., “in the wet”). Care would need to be taken to remove large pieces of concrete and to limit the downstream transport of fines. Controlling fines would be accomplished via rough notching of the dam and slowly lowering the water level in a controlled fashion. Because the dam is constructed of concrete this approach is the preferred alternative.
- Pumping / siphoning uses large diameter pipes and pumps to draw water out of the impoundment and discharge it downstream. Due to the relative small flows experienced at the sites during the preferred construction period, this method may be feasible and provide the contractor with flexibility on means and methods of removing the dam. Using a pump/ siphon system would make cofferdams unnecessary and make crossing the river less difficult (because it could be routed through a culvert under a construction access road. Negatives associated with pumps/ siphons are the cost of fuel and material.

## LIST OF TABLES:

Table 1. Alternative 5 Kinnickinnic River CAP 206 Regional Economic Development (RED) Summary.....	5
Table 2. Alternative 7 Kinnickinnic River CAP 206 Regional Economic Development (RED) Summary.....	6

## 1 General

The U.S. Army Corps of Engineers (USACE) Institute for Water Resources, Louis Berger, and Michigan State University have developed a regional economic impact modeling tool, RECONS (Regional ECONomic System), that provides estimates of jobs and other economic measures such as labor income, value added, and sales that are supported by USACE programs, projects, and activities. This modeling tool automates calculations and generates estimates of jobs, labor income, value added, and sales through the use of IMPLAN®'s multipliers and ratios, customized impact areas for USACE project locations, and customized spending profiles for USACE projects, business lines, and work activities. RECONS allows the USACE to evaluate the regional economic impact and contribution associated with USACE expenditures, activities, and infrastructure.

## 2 Description of Metrics

“Output” is the sum total of transactions that take place as a result of the construction project, including both value added and intermediate goods purchased in the economy. “Labor Income” includes all forms of employment income, including employee compensation (wages and benefits) and proprietor income. “Value Added” or “Gross Regional Product” represents the value-added output of the study regions. This metric captures all final goods and services produced in the study areas because of the existence of the project. It is different from output in the sense that one dollar of a final good or service may have multiple transactions associated with it. “Jobs” is the estimated worker-years of labor required to build the project. The secondary impacts are a summary of the multiplier effects, which include both indirect and induced effects. Indirect impacts include industries that support the direct and indirect industries spend their salaries in the impact area, creating jobs, income, and value added. The jobs and output at each level (Local, State, US) are inclusive. For example, the state job impact value contains the local job impact value within it.

## 3 Assumptions

Input-output analysis rests on the following assumptions. The production functions of industries have constant returns to scale, so if output is to increase, inputs will increase in the same proportion. Industries face no supply constraints; they have access to all the materials they can use. Industries have a fixed commodity input structure; they will not substitute any commodities or services used in the production of output in response to price changes. Industries produce their commodities in fixed proportions, so an industry will not increase production of a commodity without increasing production in every other commodity it produces. Furthermore, it is assumed that industries use the same technology to produce all their commodities. The costs were calculated using FY 2024 price levels.

## 4 Results

### 4.1 Alternative 5 RECONS Results

The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Pierce (WI) are estimated to be \$10,770,000. Of this total expenditure, \$8,042,046 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state,

and national impact areas. In summary, the expenditures \$10,770,000 support a total of 87.5 full-

time equivalent jobs, \$4,249,350 in labor income, \$5,999,302 in the gross regional product, and \$10,475,163 in economic output in the local impact area. More broadly, these expenditures support 192.5 full-time equivalent jobs, \$12,396,935 in labor income, \$16,981,595 in the gross regional product, and \$28,140,008 in economic output in the nation.

Table 1. Alternative 5 Kinnickinnic River CAP 206 Regional Economic Development (RED) Summary

Area	Output	Jobs*	Labor Income	Value Added
<b>Local</b>				
Direct Impact	\$8,042,046	69.8	\$3,686,215	\$4,835,421
Secondary Impact	\$2,433,117	17.7	\$563,134	\$1,163,881
Total Impact	\$10,475,163	87.5	\$4,249,350	\$5,999,302
<b>State</b>				
Direct Impact	\$9,586,170	92.7	\$5,631,330	\$6,480,839
Secondary Impact	\$8,235,799	45.6	\$2,688,073	\$4,597,616
Total Impact	\$17,821,969	138.4	\$8,319,403	\$11,078,455
<b>US</b>				
Direct Impact	\$10,695,014	114.0	\$6,871,848	\$7,455,914
Secondary Impact	\$17,444,994	78.5	\$5,525,087	\$9,525,681
Total Impact	\$28,140,008	192.5	\$12,396,935	\$16,981,595
* Jobs are presented in full-time equivalence (FTE). FY 2024 Price levels.				

## 4.2 Alternative 7 RECONS Results

The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Pierce (WI) are estimated to be \$19,767,000. Of this total expenditure, \$14,760,179 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures \$19,767,000 support a total of 160.6 full-time equivalent jobs, \$7,799,155 in labor income, \$11,010,976 in the gross regional product, and \$19,225,864 in economic output in the local impact area. More broadly, these expenditures support 353.3 full-time equivalent jobs, \$22,753,037 in labor income, \$31,167,613 in the gross regional product, and \$51,647,497 in economic output in the nation.

Table 2. Alternative 7 Kinnickinnic River CAP 206 Regional Economic Development (RED) Summary

Area	Output	Jobs*	Labor Income	Value Added
<b>Local</b>				
Direct Impact	\$14,760,179	128.0	\$6,765,592	\$8,874,816
Secondary Impact	\$4,465,685	32.5	\$1,033,563	\$2,136,160

## **1 Introduction**

The U.S. Army Corps of Engineers (USACE) is committed to spending the nation's dollars wisely by investing in ecosystem restoration projects that provide the greatest benefits for the investment. As such, a national ecosystem benefits analysis is completed on restoration projects to help determine if projects are warranted and if so, which combination of proposed features provide the greatest benefit for the money.

This appendix describes the methods used to quantify the benefits for various alternatives considered for the Section 206 Continuing Authorities Project (CAP) Kinnickinnic River Aquatic Ecosystem Restoration Project.

Habitat Evaluation Procedures (HEP) were used to evaluate the potential benefits of habitat improvement features (trout stream, forest, and wetland marsh restoration) for the project. Four habitat suitability index (HSI) models were used to quantify the benefits of the project area; they included: Habitat Suitability Index Models and Instream Flow Suitability Curves: Brown Trout (Raleigh et al. 1986), Habitat Suitability Index Models: Veery (Sousa 1982), Habitat Suitability Index Models: Black-Capped Chickadee (Schroeder 1983), and Habitat Suitability Index Models: Marsh Wren (Gutzwiller and Anderson 1987). The brown trout model was used to assess the existing Lake George/Kinnickinnic River and any stream restoration, the veery and black-capped chickadee models were used to assess forest restoration, and the marsh wren model was used to evaluate wetland marsh restoration.

All models and spreadsheets used to assess benefits for the project have been certified or approved for use through the Corps – Environmental Planning Center of Expertise (ECO- PCX). The Annualization calculator in IWR Planning Suite II was used to annualize benefits over the project life.

## **2 Methods Data and General Assumptions**

### **2.1 Habitat Evaluation Procedures**

The U.S. Fish and Wildlife Service's 1980 version of Habitat Evaluation Procedures (HEP) was used to quantify and evaluate the potential project effects and benefits. The HEP methodology utilizes a Habitat Suitability Index (HSI) to rate habitat quality on a scale of 0 to 1 (1 being optimum). The HSI is multiplied by the number of acres of available habitat to obtain Habitat Units (HUs). One HU is defined as one acre of optimum habitat. Benefits of different alternatives can be quantified by comparing the projected HUs available without a proposed action to projected HUs with a proposed action or alternative. HSIs and HUs were calculated for the baseline (existing) conditions and for Future Without-Project (FWOP) and Future With-Project (FWP) conditions.

### **2.2 Habitat Objectives and Model Selection**

Selection of evaluation species for a project is an important component of measuring the potential benefits of a project and comparing benefits among different alternatives. The selected evaluation species should reflect the project's objectives and the ecological values of the project area. Several objectives and opportunities were identified for the project as listed in Table 1.

Table 1. Restoration types designated to reach project objectives of the Kinnickinnic CAP 206 Project.

Habitat Areas	Project Objectives and Opportunities
<b>Trout Stream Restoration</b>  <b>(objective)</b>	1. Restore natural hydrothermal dynamics to support native cold-water species prior to impoundment. 2. Increase riffle and pool geomorphic sequence to increase the use and availability of cold-water habitat species
<b>Forest (Bottomland &amp; Mesic Forest)</b> <b>(opportunity)</b>	3. Increase riparian forest habitat.
<b>Wetland Marsh</b> <b>(opportunity)</b>	4. Increase emergent wetland habitat

The brown trout model was selected to evaluate objectives 1 and 2, as one of the primary goals of the project is to assure the continuation of the Kinnickinnic River as a Class 1 Trout Stream. A combination of the veery and black-capped chickadee models were selected to evaluate opportunity 3, as these species are often used to evaluate young and mature, respectively, forests. The marsh wren model was selected to evaluate opportunity 4, as this species is a surrogate for both shallow and deep-water marsh habitat.

## 2.3 Data Sources

Variables in the models required input from several available sources, as well as the collection, extrapolation and interpretation of additional data. Data inputs and their sources are discussed below.

### 2.3.1 Bathymetry, Topography & Ariel Imagery

Bathymetry and topography from the project area were used to categorize water depths and land elevations, respectively, within the project area. Topobathy utilizing LIDAR from 2021 of the entire area (a combination of both bathymetry and topography) from the Wisconsin DNR was used to analyze and delineate the entire project area. Additional, aerial imagery from multiple sources and years were used to inform some inputs for habitat modeling.

### 2.3.2 Water Quality

Water quality, specifically dissolved oxygen, and water temperature were used to assess lake and stream habitat quality throughout the project area.

### 2.3.3 Hydraulic Velocity

Hydraulic modelling, specifically for water velocity, peak flow and low-flow periods were used to assess the existing condition, FWP and FWOP throughout the project area. This information was modeled by the Corps through the Hydrologic Engineering Center's River Analysis System (HEC-RAS 6.2).

## **2.4 Software**

ArcGIS Pro version 3.2.0 was used to examine, evaluate, and present the various layers of spatial information used to develop suitability indexes for a variety of habitat variables. Spreadsheets developed in Microsoft Excel were used in data storage and analysis. The IWR Planning Suite Annualization Calculator was used to annualize habitat units. The IWR Planning Suite software to conduct cost effectiveness and incremental cost analysis is discussed and presented in the main report.

## **2.5 Alternative Groups and Analysis Areas**

The project area was divided into sub-areas that were used to evaluate the different project alternatives (Figure 1). Using sub-areas focused habitat evaluation to manageable areas that could be evaluated based on the different project alternatives. If certain elements were not evaluated, then habitat evaluation areas could be removed from the HEP analysis for a given project alternative. Also, using sub-areas ensured that benefits were only attributed to specific acreages once, preventing the double-counting of benefits. Depending on which dam would be removed under a project alternative, the number of acres could change throughout these complexes. The breakdown of the HSI acres that were analyzed between the different project alternatives during feasibility are shown in Tables 5 and 6 at the end of Section 3.4.

## **2.6 General Assumptions**

Predicted FWOP and FWP conditions are used in the planning of all Corps restoration projects. These predictions are used to quantify the expected habitat benefits for use in alternatives evaluation and project justification. Predictions are based on factual information as much as possible; however, by their very nature, predictions require the considerable use of professional expertise and judgment. For this analysis, a number of general assumptions were made as follows:

1. A 50-year planning period is used. Because construction of this project would not begin until at least 2027, and likely not be complete until 2029, the planning period for this project is 2029-2079.
2. The projection of FWOP conditions assumes no habitat restoration measures would occur in the study area and natural forces would continue to change the area in a manner similar to what has occurred since Junction Falls Dam was constructed in the early 1900s and Lake Louise was drained in 2021.
3. Habitat benefits associated with changes in vegetation composition and extent would be realized within 3 years of construction for aquatic areas, specifically those geared toward emergent wetland/marsh (marsh wren).
4. River restoration features are designed to reach optimal variable values for brown trout (i.e., velocity, water depth, flow).

Figure 1. Kinnickinnic River sub-areas that were used to analyze the different alternatives of the project.

Figure 2. Kinnickinnic River HEP models used to analyze the different alternatives for the project.

### 3 Habitat Suitability Modeling

#### 3.1 Trout Stream Habitat Suitability Index Modeling

##### 3.1.1 Model Selection and Variables

The Kinnickinnic River is currently a Class 1 trout stream according to the Wisconsin Department of Natural Resources, which is the highest designation. Class 1 trout water signifies the highest quality possible trout waters that have sufficient natural reproduction to sustain wild trout populations that are at or near carrying capacity. As such, these streams do not require stocking of hatchery trout. The Kinnickinnic River contains an exceptionally high density and quality brown trout population, making it one of the best brown trout fisheries in the country. Native brook trout are found within certain stretches of the Kinnickinnic river, with brook trout representing the main trout species within the South Fork of the Kinnickinnic River. One of the larger concerns with habitat suitability on the Kinnickinnic River through River Falls is the increased water temperature due to water retention from Junction Falls Dam (Lake George). Even with the lowering of Lake Louise in 2021 and the associated lowering temperatures within the Kinnickinnic River below the dam, there are times when water temperatures are above the optimal temperature range for trout species (66.2°F, Kiap-TU-Wish 2023). If water temperature is elevated or increases through time, it could act as a limiting factor for trout suitability.

To quantify cold-water trout habitat within the Kinnickinnic River project area under the existing condition, the FWOP condition, and FWP condition, the Habitat Suitability Index Models and Instream Flow Suitability Curves: Brown Trout (Raleigh et al. 1986), or herein brown trout model, was used. This model looks at different life stages of trout, flow requirements, substrates, canopy cover and water quality variables to provide an HSI score. In total this model utilizes 18 variables, 13 of which are required for analysis, while 5 are optional. For this project the brown trout model was used as a surrogate to represent other native trout species (i.e., brook trout) and quantify cold-water stream habitat quality. Variables of the model include the following:

- **V1** - Maximum water temperature (°C) during the warmest period of the year (adults and juveniles)
- **V1** - Maximum water temperature (°C) during the warmest period of the year (fry)
- **V2** - Maximum water temperature (°C) during embryo development
- **V3** - Minimum dissolved oxygen (mg/L) during the late growing season, low-water period and during embryo development ( $\leq 10^{\circ}\text{C}$ )
- **V3** - Minimum dissolved oxygen (mg/L) during the late growing season, low-water period and during embryo development ( $> 10^{\circ}\text{C}$ )
- **V4** - Average velocity (cm/s) over spawning areas during spawning and embryo development
- **V5** - Percent cover during the late growing season, low-water period at depths  $\geq 15$  cm and near bottom velocities  $< 15$  cm/s (juveniles)
- **V5** - Percent cover during the late growing season, low-water period at depths  $\geq 15$  cm and near bottom velocities  $< 15$  cm/s (adults)
- **V6** - Percent of total study area consisting of two spawning gravel size classes (1 to 7 cm)
- **V6** - Percent of total study area consisting of two spawning gravel size classes (0.3 to  $< 1$  cm and  $> 7$ -10cm)
- **V7** - Percent of substrate as size class (10 to 40 cm) used for winter and escape cover by fry and small juveniles
- **V8** - Dominant ( $\geq 50\%$ ) substrate type in riffle-run areas for food production
- **V9** - Percent pools during the late growing season, low-water period

## Appendix K: Habitat Evaluation Procedures

- **V10** - Average percent vegetation (trees, shrubs, and grasses-forbs) along the streambank during the summer for allochthonous input ( $2 \times \% \text{ shrubs} + 1.5 \times \% \text{ grasses} + \% \text{ trees} + 0 \times \% \text{ bare ground}$ )
- **V11** - Average percent rooted vegetation and stable rocky ground cover along the streambank during the summer (erosion control)
- **V12** - Annual maximal or minimal pH. Use measurement with lowest SI.
- **V13** - Average annual base flow regime during late summer or winter low-flow period as a percentage of the average annual daily flow (cfs)
- **V14** - Pool class rating during late growing season, low-flow period. Based on % of area that contains pools of the three described classes
- **V15** - Percent fines (<3mm) in spawning areas during average summer flows
- **V15** - Percent fines (<3mm) in riffle-run areas during average summer flows
- **V16** - Percent of stream area shaded between 1000 and 1400 hrs (for streams  $\leq 50\text{m}$  wide). Do not use for cold (<18 degrees C), unproductive streams
- **V17** - Levels of late summer nitrate-nitrogen in mg/L
- **V18** - Average annual peak flow as a multiple of average annual daily flow. For embryo and fry habitat suitability, use the average and highest flows that occur from time of egg deposition until two weeks after fry emergence.

### 3.1.2 Brown Trout HSI Model Results

#### 3.1.2.1 *Existing Conditions and Future without Project*

Under the existing and Future without Project (FWOP) conditions Junction Falls Dam is and would remain in place, maintaining the Lake George impoundment. Any habitat evaluated for brown trout within the Lake George basin has an HSI value of zero due to the low velocity (cm/s) within this habitat area (V4). Low velocities throughout Lake George is acting as a limiting factor in the model for potential spawning areas, as this level of velocity would not allow brown trout embryos to properly develop. Habitat suitability in the Lake Louise sub-area would be marginal (0.3) for much of this timeframe due to the lack of adequate substrate types. Other limiting variable through this river reach include percent cover ((V5 (adults))) and rooted vegetation and stable rocky ground cover (V11). The existing and FWOP condition for the Lower Kinnickinnic, which was evaluated to track water quality benefit only, is quite suitable (0.7 avg), with some loss of suitability due to increased temperature near the end of the project evaluation.

#### 3.1.2.2 *Future with Project*

Under the FWP, Junction Falls Dam would be removed, along with the Lake George impoundment. Through this action, the habitat evaluated for brown trout would get immediate benefits from decreased water temperature, increased dissolved oxygen and optimal velocities. The proposed project would incorporate stream restoration features of riffles, pools, rock arch rapids, cross vanes, and Lunker structures throughout the entire river within the project area. Stream restoration features would be designed to provide optimal habitat for brown trout based on the HSI model. These features, along with the water quality benefits would provide higher suitability for all sub-areas evaluated under the model (Table 2). Finally, the FWP would provide water quality benefits (lower water temperature and increase dissolved oxygen) to the Lower Kinnickinnic River due to dam removal. To account for other cold-water inputs and dilution through the Lower Kinnickinnic, a decreasing percent benefit gradient was incorporated to account for a loss of benefits as the river gets closer to the confluence.

### 3.1.3 Brown Trout HSI Model Results Summary

Table 1 shows how the brown trout (trout stream) HSI changes over the project planning period of 50 years using the brown trout HSI model. These numbers were used in generating AAHUs for each alternative for the project (See Section 3.4, Tables 5 & 6).

## 3.2 Forestry Habitat Suitability Index Modeling

### 3.2.1 Model Selection and Variables

Forests take a long time to reach maturity. Trees planted or naturally seeded take at least fifty years to develop mature forest features. In the intervening time, the plant community undergoes several successional changes from an open herbaceous community with small seedlings to a dense stand of young saplings to a stand of young trees to a stand of mature trees beginning to differentiate in size, height, and structure. The successional pathways vary considerably by forest type. Mature forests develop unique characteristics such as large woody debris, standing snags, emergent trees, multi-layered canopy, and understory regeneration.

Because the forest undergoes such significant changes over the planning period, two models were used to evaluate the forest habitat. The veery model, which considers the value of shrubs and herbaceous plants, was used for young forests, using years 1, 10, and 20. The mature forest was evaluated at years 30, 40, and 50 using the chickadee model, which considers the value of canopy closure, tree height, and snags. Forestry benefits were analyzed among newly forested areas that would be built in riparian corridor of the project.

### 3.2.2 VEERY MODEL

The veery model was chosen to quantify the benefits provided by newly constructed floodplain forest for the first twenty years of the project. Veeries, a species of small woodland thrush, (*Catharus fuscescens*) prefer thick shrub and herbaceous cover in moist or wet woodlands and shrub wetlands. For a deciduous floodplain forest, optimal conditions in the model include:

- a. A flooding regime that does not flood the habitat in spring and early summer.
- b. At least 70% deciduous shrub crown cover.
- c. Average deciduous shrub height between 1.5-3 m.
- d. Herbaceous canopy cover over 90%.
- e. Herbaceous canopy height over 30 cm.

### 3.2.3 CHICKADEE MODEL

The chickadee model was chosen to quantify the benefits provided by mature floodplain forest. The black-capped chickadee (*Parus atricapillus*) inhabits wooded areas throughout North America, and nests in dead or hollow trees. The chickadee is insectivorous and selects territories based on the potential abundance of food, determined primarily on canopy volume. Optimal conditions in the black-capped chickadee model include:

- a. Tree canopy closure of 50 to 75 percent.
- b. Average height of overstory trees is greater than 15 meters.
- c. Two or more snags 10 to 25 cm diameter breast height (dbh) per acre.

### **3.2.4 Veery/Chickadee HSI Results**

#### **3.2.4.1 Existing and Future without Project Conditions**

Within Lake George, the existing and FWOP conditions where riparian floodplain forest restoration would happen are currently aquatic (impoundment). This area would have HSI values of zero for each veery and chickadee variables, as it is inundated, and there are no shrubs or herbaceous canopy cover. Much of the other current terrestrial habitat evaluated for forest suitability is currently devoid of trees. The Lake Louise sub-area was once impounded, and proper restoration has not taken place since the lake was drained in 2021; this has resulted in the area being dominated by reed canary grass and other invasive species. Without intervention, suitability for veery and chickadee is anticipated to remain low, with some benefits around the 20-year evaluation period, with a dip in year 30 and on because of a lack of canopy cover and snags.

#### **3.2.4.2 Future with Project**

The early stages of forestry measures within the restored riparian corridor would provide early successional forest conditions, which is evident through shrubs and shrub-like trees. Tree seedlings and shrubs would be planted within restoration areas classified as bottomland and mesic forest. In Year 1, the habitat values would remain relatively low as the trees and shrubs become established. For the first twenty years the young trees would fill the same functional niche as shrubs. At year 20, the trees and shrubs form distinct layers. At this time, the young trees are no longer included in the shrub crown cover, but planted shrubs still provide optimal cover for veery HSI. At year 30, the herbaceous layer becomes less dense as the closing forest canopy shades it out. The transition from Veery to chickadee at year 30 causes the HSI scores to decline, as forests are still not mature. Trees reach maturity by year 50, indicating a high suitability of chickadee, representing highly productive forest habitat.

### **3.2.5 Veery/Chickadee HSI Model Results Summary**

Table 3 shows how the forestry HSI changes over the project planning period of 50 years using the veery and chickadee HSI model. These numbers were used in generating AAHUs for each alternative for the project (See Section 3.4, Tables 5 & 6)

## Appendix K: Habitat Evaluation Procedures

### **3.3 Wetland Marsh Habitat Suitability Index Modeling**

#### **3.3.1 Model Selection and Variables**

The marsh habitat designed as part of the project would be Type 3 wetlands that consist of emergent aquatic plants that include grasses, bulrushes, cattails and arrowheads and provide habitat for waterfowl, herptiles small mammals, and fish. The bottom elevation of the marsh areas would be set to the elevation of the bottom of the Kinnickinnic River main channel, allowing the area to fall below the water table. The marsh wren model is ideal for evaluating increases in aquatic vegetation that would result from reduction of water velocities, and inundated areas that are ideal for emergent aquatic plants. This model was selected to measure the benefits associated with improving marsh or wetland habitat through restoration. The marsh wren HSI model consists of four simple variables that assess the habitat value of the type of vegetation and water depth of an area. Two specific areas covering a total of 2.67 acres, as seen in Figure 2, were evaluated using this HSI model.

Optimum conditions described in the model are as follows:

- a. Growth form of emergent hydrophyte is bulrushes, cattails, and sedges.
- b. Percent canopy cover of emergent herbaceous vegetation is 80% or greater.
- c. Mean water depth is 15cm or greater.
- d. Percent canopy cover of woody vegetation is zero.

#### **3.3.2 Marsh Wren HSI Model results**

##### **3.3.2.1 Existing and Future without Project Conditions**

The marsh wren model was applied to areas that would be constructed as wetland marsh habitat as part of the project. The current evaluation area of marsh wren within the Lake George sub-area within the impoundment area is void of emergent hydrophytes and herbaceous cover, resulting in an HSI of zero. By the end of the evaluation period, some emergent hydrophytes would be present in Lake George due to lake succession, resulting in some suitability for the marsh wren. The marsh habitat within the Lake Louise sub-area is not inundated and does not contain emergent hydrophytes, resulting in an HSI of zero. This area is anticipated to stay the same under the FWOP.

##### **3.3.2.2 Future with Project**

As part of the project, wetland marsh habitat would be designed as a type 3 wetland or shallow marsh through excavating to the water table. Marsh habitat vegetation would include grasses, bulrushes, cattails and arrowheads. Suitability at year 1 would be low due to the lack of emergent hydrophytes and herbaceous canopy cover. Emergent vegetation and canopy cover are expected to be greatly improved by year five years of the evaluation window. By year 50 herbaceous cover would be optimal, water depth would be slightly decreased due to sedimentation and woody canopy cover would be present due to the adjacent forest habitat.

#### **3.3.3 Marsh Wren HSI Model Results Summary**

Table 4 shows how the wetland marsh HSI changes over the project planning period of 50 years using the marsh wren HSI model. These numbers were used in generating AAHUs for each alternative for the project (See Section 3.4, Tables 5 & 6)

Table 4. Marsh wren HSI model results summaries.

<b>Sub-Area</b>	<b>Alternatives Present</b>	<b>Acres</b>	<b>TY0 HSI</b>	<b>TY1 HSI</b>	<b>TY5 HSI</b>	<b>TY50 HSI</b>
Lake George	No Action	1.34	0.00	0.00	0.00	0.37
Lake George	Alts 2, 4, 5, 7	1.34	0.00	0.16	0.74	0.90

Lake Louise	Alts 3, 4, 6, 7	1.33	0.00	0.16	0.74	0.90

### 3.4 Combined Habitat Units Results

Habitat units (HUs) are the product of the HSI value and acres of a given area, such that one habitat unit is one acre of habitat with a perfect HSI score of one. It is important to accurately quantify the acres of a given habitat type for each alternative being assessed. Table 5 summarizes the acres of habitat analyzed for each habitat model across the different alternatives. The maximum acres evaluated for the project was 121.2 acres. Evaluation acres per habitat model was multiplied by the HSI values for each target year and averaged over the 50-year project life. The resulting Average Annual Habitat Units (AAHUs) for each habitat model for each alternative is depicted in Table 6. The gain in AAHUs over the existing and FWOP condition for each project alternative are shown as incremental gains for each alternative. Incremental net gains of AAHUs were used in the Cost Effectiveness/Incremental Cost Analysis (CE/ICA) found in the main report and helped in determining the Tentatively Selected Plan for the project. The detailed HSI model inputs and calculations are available upon request.

## Appendix K: Habitat Evaluation Procedures

Table 5. Acres of habitat evaluated for each HSI model per alternative.

Alternative	Analysis	Acres Per Habitat Type			Total
		Brown Trout	Veery/Chickadee	Marsh Wren	
Alt 2	No Action	86.0	10.5	1.3	97.8
	Alt 2	86.0	10.5	1.3	97.8
Alt 3	No Action	5.0	17.4	1.3	23.7
	Alt 3	5.0	17.4	1.3	23.7
